INTRODUCTION

With changes in the ecosystem caused by the on-going climate change, biodiversity in the respective regions of the ecosystem have also been subject to change. In particular, as vegetation in the Arctic region has shown extra sensitivity to the effects of climate change, it must be continually monitored as indicators of climate change. However, there are lots of obstacles to conduct continuous vegetation monitoring in detail through field work in the Arctic region. For this reason, satellite data was developed to allow research in the regions inaccessible to field work. The objective of this study is to construct the vegetation map of the Midtre Lovénbreen, in Svalbard, Norway and to observe long-term variation of vegetation using remote sensing images.

PREVIOUS STUDIES IN MIDTRE LOVÉNBREEN

Subglacial ecosystem (ice-bed interface)

• Glacier-bed characteristics by radar (King *et al.*, 2008)

- Glacier river system-nitrogen (Hodson *et al.*, 2010)
- Plant succession: Laffly/Brossard/ Nilsen
- Plant and soil succession (Hodkinson *et al.*, 2003)
- Characteristics of SOC by pyrolysis GC-MS (White *et al.*, 2007)
- Microbial community structure (Schuette *et al.*, 2009, 2010)
- Weathering of rocks by pioneer microbes (Borin *et al.*, 2010)

MATERIALS & METHODS

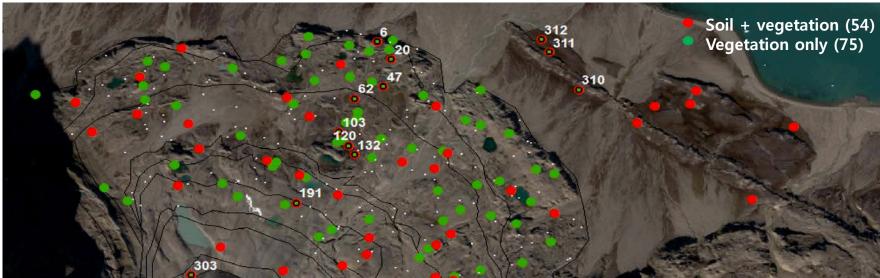

Satellite image

We will use Formosat-2 and Pleiades 1A satellite image.

Satellite	Formosat-2	Pleiades 1A
Launch date	2004.05.21	2011.12.16
Spatial Resolution	Pan(B&W) : 2m MS : 8m	pan(B&W):50cm MS:50cm
No. of band	4 (B, G, R, NIR)	4 (B, G, R, NIR)
Revisit interval	Daily	Daily
Swath width	24km	20km

STUDY AREA

• Study area: Glacier foreland of Midtre Lovénbreen, Brøgger Peninsula, Svalbard, Norway (79°N, 12°W)

Both of these satellite images are high-resolution and as both carry NIR band, are well-suited to make observations of vegetation states.

• Vegetation survey sites:

- All dots for the sites that Moreau et al. (2005) covered
- Green and red dots for the sites in 2014

* Methods

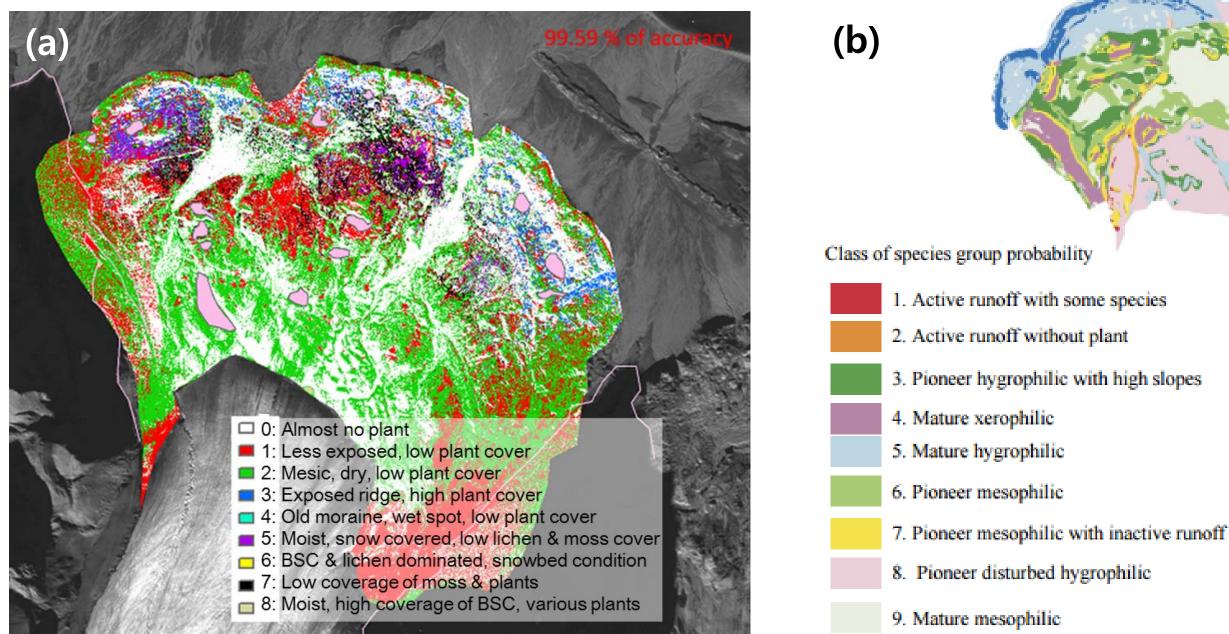

While moss and lichen are dominant in the Arctic region, observation and analysis using satellite imaging is difficult due to their small and sparse distribution.

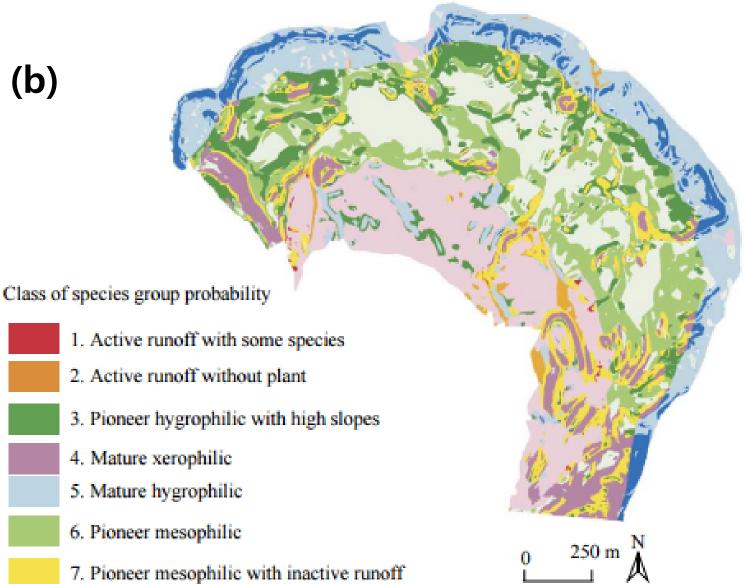

To improve limits in spatial resolution, several methods will be used.

- 1. Minimum Noise Fraction (MNF): to minimize the dimensionality and noise;
- 2. Pixel Purity Index (PPI): to collect the endmember
- 3. Spectral Mixture Analysis (SMA): to confirm the abundance of vegetation.

Verification of results acquired from satellite images

These results using remote sensed images will be confirmed by comparing the field data acquired in July 2014 and a vegetation map from Moreau et al. (2005).

). Mature xerophilic with high slopes
